# Spotting a Supernova

Background Material

## Gaia Science Alerts

*The detection of transient astronomical objects in real-time*

Not all stars emit light with a constant brightness and radiation output, many of them **change in brightness very suddenly** and often unexpectedly, over a variety of timescales. We call these objects **transients**.

Every day, the Gaia team announces several **science alerts** which indicate new discoveries of transient objects. The discoveries themselves are made in Cambridge University at the data processing centre at the Institute of Astronomy. Here, they lead the UK's involvement within the Gaia Data Processing and Analysis Consortium (DPAC).

As most transients – and indeed stars – that Gaia sees are so far away from us and appear so faint, we are unable to see them with the naked eye alone. Gaia is mapping one billion stars, whereas fewer than ten thousand stars are bright enough to be seen with just the naked eye – and most of those only with very dark sky conditions!) However, these objects can be seen from the ground by harnessing the power of **robotic telescopes** such as the Faulkes Telescopes. Gaia's science alerts (GSA) provide accessible data that **schools** and amateurs can use to make their own follow-up observations to confirm these transient objects and gather more information about their **properties and characteristics**.

## The Expansion and Age of the Universe

*Using type Ia supernovae to calculate the expansion and age of our Universe*

We can use type Ia supernovae to help us determine how quickly our Universe is expanding and also, how old it is! This activity involves combining your own data with other scientific data to calculate these values.

If you have completed the Spotting a Supernova activity, you can use your results to **contribute to the data** in this activity.

If you haven't, you can still complete this activity with the data provided.

### Measuring Peak Magnitudes of Type Ia Supernovae

Now that you are familiar with carrying out photometry, let's take a look at some data from some other type Ia supernova targets.

**Step 1:** First of all, you will need a table to record your results in. Use the space below to design a table that you can use to record the parameters listed below. When you are happy with it, copy it

# Hubble Diagram

# Ideal Target Checklist

Supernova (Type Ia)

Bright

Recent

Visible (for next few weeks)

In spiral galaxy

Easy to photometrise

Can we make (some of) this a coding challenge and use Python to create a list from the Gaia Alerts .csv ?

# New in 2018

The return of real-time observing

NRES (Network of Robotic Echelle Spectrographs)

USP for 2-metre telescope

High resolution ( $R \sim 50,000$ ) spectrographs on 1-metre telescopes

Schools get exclusive control of telescopes for 30 minute blocks

# New (since yesterday !)

## FAULKES TELESCOPE PROJECT

[Observing](#)[Resources](#)[Showcase](#)[Information](#)[Projects](#)[Support](#)[News](#)

### WHO ARE WE?

The Faulkes Telescope Project provides free access to a global network of robotic telescopes for education through our partnership with Las Cumbres Observatory. We also offer free teacher CPD, classroom resources and advice and support on all aspects of using astronomy in your classroom.

[Find out more](#)

### LOGIN OR REGISTER

Registration and use of the telescopes is free for UK school teachers and educators and partner organisations in Europe. Click the button below to register for a new account, or click the login button to access your account and use the telescopes. If you are based elsewhere in the world, please contact us if you'd like to discuss working with us.

[Login](#)[Register](#)

### WHAT DO WE OFFER?

The Faulkes Telescope Project offers free resources for STEM education and provides free access to a global network of telescopes. Spot new supernovae, catch a comet, gaze at galaxies - bring the Universe to your classroom and carry out real research with astronomers!

MAXI J1820+070 (ASASSN-18ey) is a black hole candidate X-ray binary (e.g. ATel #[11399](#), #[11418](#), #[11420](#)). It is currently in a bright, hard spectral state (ATel #[11423](#), #[11427](#), #[11439](#)). Here, we report photometric mid-IR (5-12  $\mu\text{m}$ ) observations of the source with the VLT Imager and Spectrometer for the mid-InfraRed (VISIR; Lagage et al. 2004, The Messenger, 117, 12) mounted on UT3 of ESO's Very Large Telescope. The observations were made on 2018 April 8 (07:21-08:08 UTC) and April 9 (08:54-09:41 UTC) in clear conditions (MJD 58216-7). We also report on contemporaneous radio and optical data. MAXI J1820+070 is clearly detected (S/N > 200) in all four mid-IR filters. The following preliminary observed flux densities ( $F_{\nu}$ ) were calculated using observations of standard stars taken on the same nights:
